

Recrystallization – *practical considerations*

Progressive approach:

- 1) solvent selection on micro-scale (~20 mg)
- 2) medium batch ($^{\sim}100 200 \text{ mg}$)
- 3) large batch (\sim 3 5 g) + also involves hot filtration

Solvent selection

- sample must be completely <u>dry</u>!
- careful, detailed observations are crucial!
- begin with 20 mg in ~0.1 mL solvent; incrementally add more solvent
- if > 1.0 mL solvent required, solvent is not suitable

Solvent choices

- water
- ethanol (CH₃CH₂OH)
- hexane (CH₃CH₂CH₂CH₂CH₃)
- toluene (methylbenzene)

<u>Mixed solvent systems</u>

water/ethanol

hexane/toluene

Recrystallization – *practical considerations*

Common "pitfalls":

1) crystals do not form

seed crystal
"scratching"
too much solvent?

2) crystals are of insufficient purity

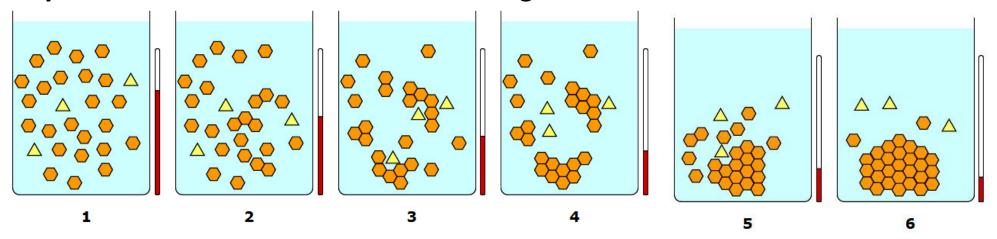

was solution cooled slowly?
inappropriate solvent
sample "melting" at boiling point of recrystallization solvent

3) low recovery

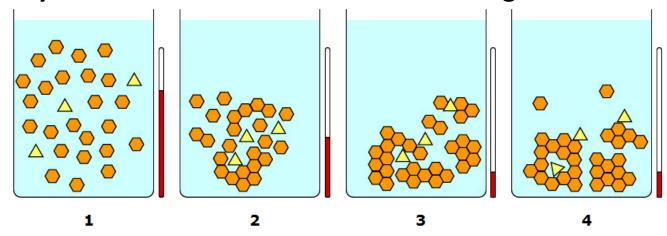

filtrate (mother liquor) contains compound of interest too much solvent? insufficient cooling

Recrystallization

Crystallization that occurs with slow cooling:

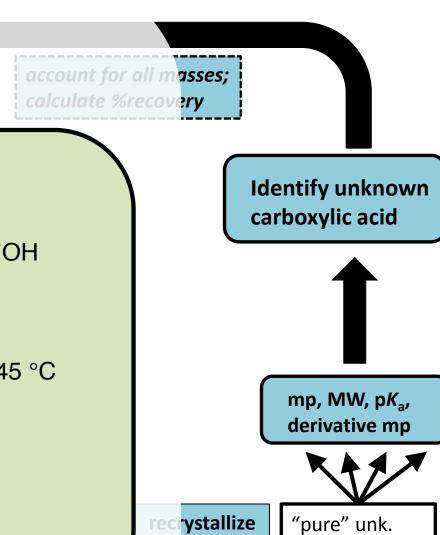

Crystallization that occurs with fast cooling:

sodium salt of unknown aromatic carboxylic acid + soluble impurities + insoluble impurities total mass: ? g

carboxylic acid

mass: ? g

melting point ("mp")

sodium salt of unknown aromatic carboxylic acid + soluble impurities + insoluble impurities total mass: ? g

account for all masses; calculate %recovery

 $C_7H_5BrO_2$

mol. wt. = 201.02

 $C_7H_4Cl_2O_2$

mol. wt. = 191.01

Identify unknown carboxylic acid

mp, MW, p K_a , derivative mp

recrystallize

"pure" unk. carboxylic acid mass: ? q

melting point ("mp")

sodium salt of unknown aromatic carboxylic acid + soluble impurities + insoluble impurities total mass: ? g

account for all masses; calculate %recovery

C₇H₅BrO₂

mol. wt. = 201.02

$$pK_a = 2.85$$

 $C_7H_4CI_2O_2$

mol. wt. = 191.01

$$pK_a = 1.82$$

Identify unknown carboxylic acid

mp, MW, pK_a , derivative mp

recrystallize

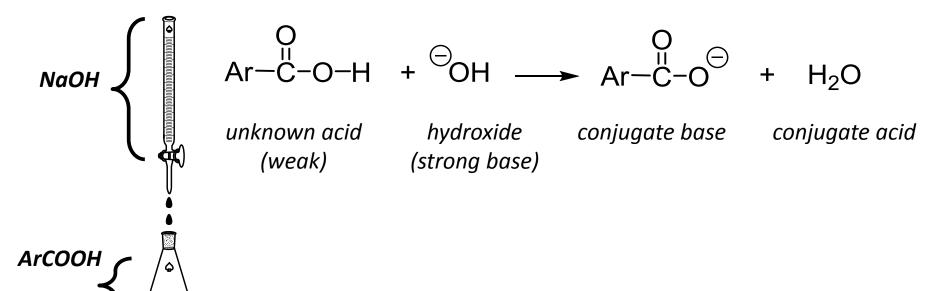

"pure" unk. carboxylic acid mass: ? q

melting point ("mp")

Titration

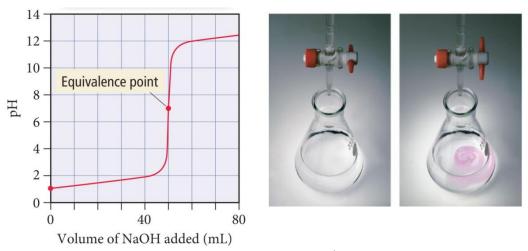

Method to determine the concentration of an analyte, through the slow, incremental addition of a known concentration of another reagent

Acid-Base Titration:

Determining the Equivalence Point:

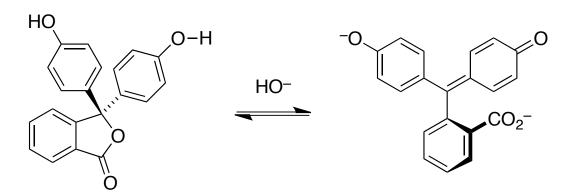

- pH vs. vol. NaOH added (potentiometric)
- Color change of pH indicator (end-point)

Figures from "Principles of Chemistry: A Molecular Approach, 2nd Edition" by N. Tro (Pearson)

End-Point Titration

- data allows calculation of equivalent weight of unknown acid
 (for a monoprotic acid, equivalent weight = molecular weight)
- Phenolphthalein is the end-point indicator you will use
 ** unless you are colorblind to red **
 (if so, inquire about alternative indicators)

phenolphthalein colorless: pH 0 to 8.2

phenolphthalein: dianion form pink: pH 8.2-12.0

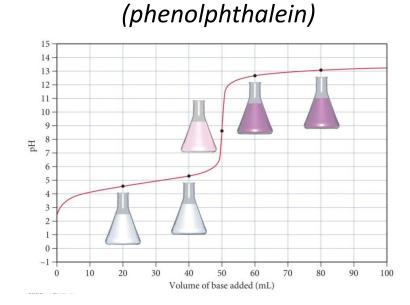

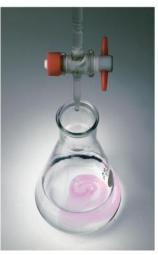

Figure from "Principles of Chemistry: A Molecular Approach, 2nd Edition" by N. Tro (Pearson)

Titrations must be carried out carefully!

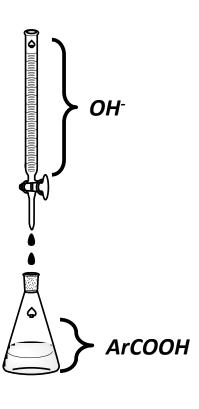

- obtain accurate mass of unknown
- acid must be completely dissolved
 (~0.3 g/50 mL; can add some ethanol if needed)
- proper buret reading
- may need to add fraction of a drop of NaOH solution
- must obtain 2 measurements within 0.5% of each other
- do not "overshoot" the end-point

 make all measurements to 4 significant figures

Example calculation and consequences of errors

• 254.2 mg of dry purified acid titrated with 0.1033 N aq. NaOH

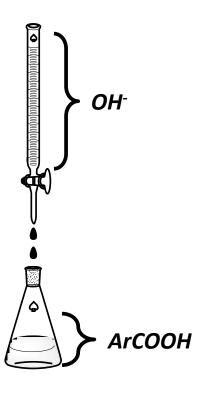

end-point reached upon addn. of **12.24 mL** of base

mmols of base = 0.1033 mmol mL⁻¹ x 12.24 mL

= 1.264 mmol

mol. wt. of acid = 254.2 mg / 1.264 mmol

 $= 201.11 \text{ g mol}^{-1}$

OH
Br

$$CI$$
 OH
 CI
 OH
 OH

Example calculation and consequences of errors

• 254.2 mg of dry purified acid titrated with 0.1033 N aq. NaOH

mmols of base = $0.1033 \text{ mmol mL}^{-1} \text{ x } 12.24 \text{ mL}$

= 1.264 mmol

 $= 201.11 \text{ g mol}^{-1}$

true mol. =
$$241.5 \text{ mg} / 1.264 \text{ mmol}$$

wt. of acid = $191.05 \text{ g mol}^{-1}$

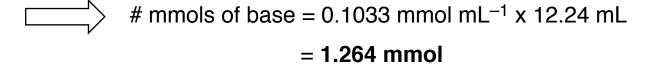

O
$$CI$$
 OH
Br CI OH
 CI O

Example calculation and consequences of errors

• 254.2 mg of dry purified acid titrated with 0.1033 N aq. NaOH

 $= 201.11 \text{ g mol}^{-1}$

BUT, what if we over shot end-point? e.g., true value 12.00 mL

true mol.
$$= 254.2 \text{ mg} / 1.240 \text{ mmol}$$

wt. of acid $= 205.00 \text{ g mol}^{-1}$

OH
Br

$$CI$$
 OH
 CI
 OH
 OH

Potentiometric Titration

• data allows determination of pK_a of unknown acid

$$Ar-C-O-H + H_2O \longrightarrow Ar-C-O + H_3O^{\oplus}$$

$$K_a = \frac{[ArCOO^-][H_3O^+]}{[ArCOOH]} \qquad pK_a = -log(K_a)$$

• as hydroxide is added, a buffer system develops

Ar-C-O-H + OH
$$\longrightarrow$$
 Ar-C-O + H₂O
$$pH = pK_a + log\left(\frac{[ArCOO^-]}{[ArCOOH]}\right)$$

• when $[ArCOO^{-}] = [ArCOOH]$, pH is equal to the p K_a of the unknown acid

Potentiometric Titration

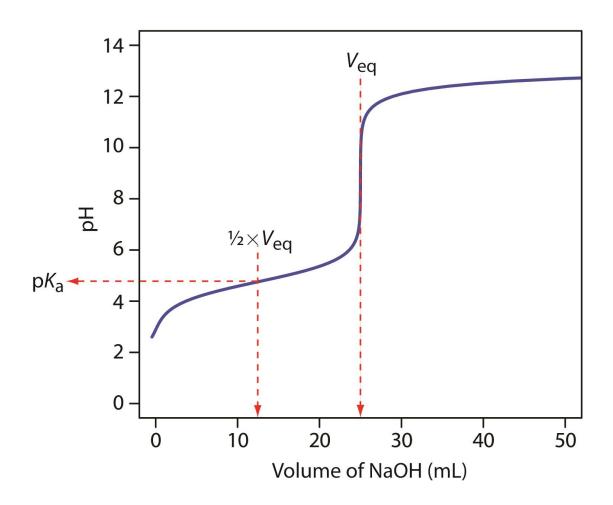

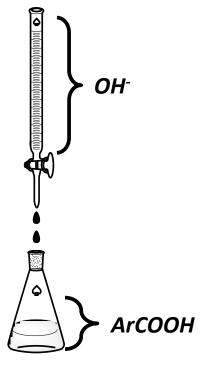

Figure downloaded from UC Davis ChemWiki website

Potentiometric Titration: *Practical Considerations*

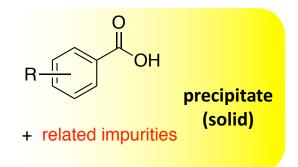

- prepare a solution of ~100 mg in 100-150 mL
- acid must be completely dissolved
 (ethanol will obscure results use only if needed)
- heat solution to aid dissolution
 do not begin titration until solution has cooled to 25°C
- interpret pK_a data with caution

Tasks for Week 2: Trial, Medium, and Large Batch Recrystallizations

- polar non-ionic compound
- sparing solubility in H₂O

Wednesday

conclude trial recrystallizations and apply selected solvent to medium batch – check
 % recovery, if ca. ≥75%, solvent system OK for large batch (rest of material)

Wed./ Fri.

 large batch recrystallization, collect and dry material (oven), need ca. 4 g (after drying to constant weight), accurrately determine melting point of pure acid

(Friday)

• TIME ALLOWING – begin end-point titrations
