1 Preliminary Steps for ssh

OpenMX software runs on the computers in Weniger 412 in a Linux environment, but it is convenient to be able to run the software remotely from any machine. The best way to remotely access the software is through Secure Shell (ssh), and in order to do this on a Mac or Windows machine there are a few important steps that need to be taken first.

1.1 Installation of ssh software on Windows

Windows does have built in ssh software, but because we are interfacing with programs that have guis, it is best to use third party ssh software that makes that easy. To give windows the tools that it needs, you need to install putty (a simple ssh tool) Xming (a graphics environment for streaming Linux programs over ssh). Please follow the installation steps below.

Putty Installation –

Navigate your browser to <http://www.chiark.greenend.org.uk/~sgtatham/putty/latest.html> and click the link for the .msi file that corresponds to your version of Windows, then follow the default installation.

Xming Installation –

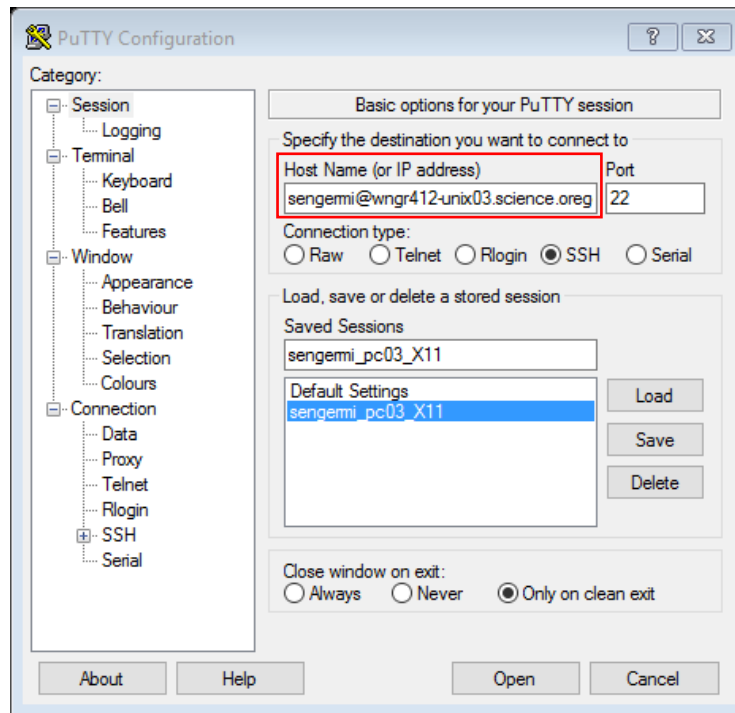

Download Xming from Sourceforge here: <https://sourceforge.net/projects/xming/files/latest/download>. Again, follow the default installation options.

1.2 Starting an ssh session with the 412 computers from Windows

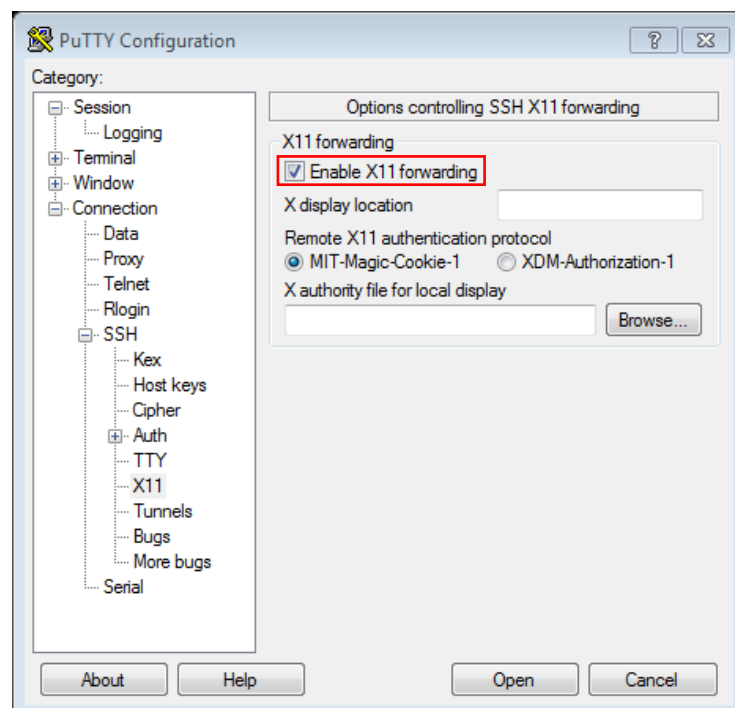

First, launch Xming. Xming will now run in the background. No windows will pop up, but you should see the Xming icon appear in the system tray.

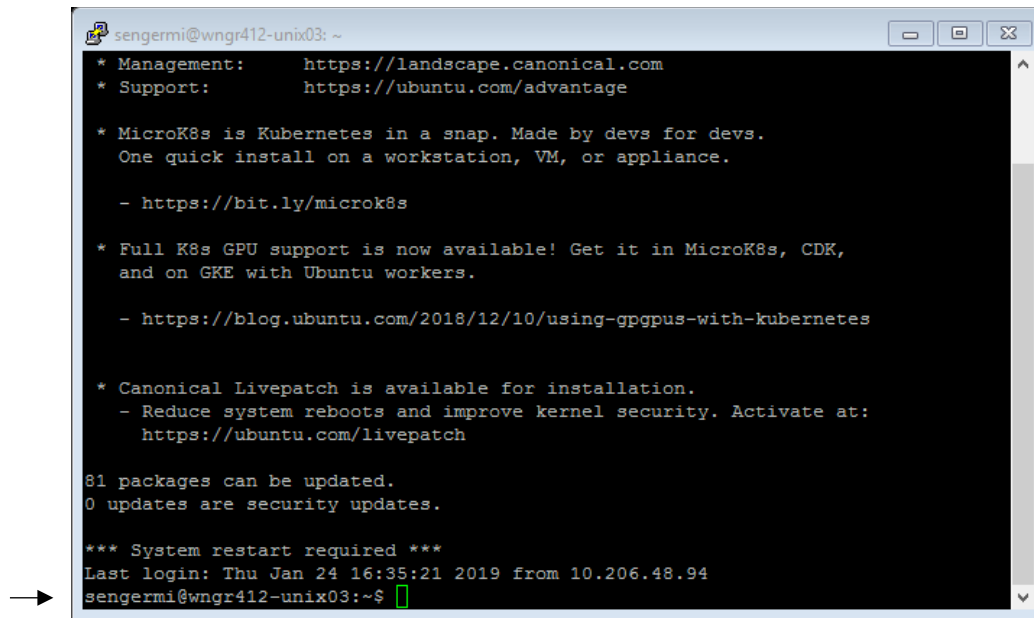

Now that Xming is running, launch putty. In the Host Name box, enter the address of your user account at the Weniger 412 computer you will be using in the form **ONID@wngr412-unixXX.science.oregonstate.edu**, where **ONID** is your onid username and **XX** is the PC number assigned to you.

Before opening the connection, navigate the category panel to Connection>SSH>X11, then check the box to “Enable X11 forwarding”.

Now click the “Open” button to connect to the 412 PC over ssh. You’ll get a security warning – just click “Yes” to allow the connection, then enter your assigned password. You should then see the command line for your PC appear.

```

sengermi@wngr412-unix03: ~
* Management:      https://landscape.canonical.com
* Support:         https://ubuntu.com/advantage

* MicroK8s is Kubernetes in a snap. Made by devs for devs.
  One quick install on a workstation, VM, or appliance.

  - https://bit.ly/microk8s

* Full K8s GPU support is now available! Get it in MicroK8s, CDK,
  and on GKE with Ubuntu workers.

  - https://blog.ubuntu.com/2018/12/10/using-gpgpus-with-kubernetes

* Canonical Livepatch is available for installation.
  - Reduce system reboots and improve kernel security. Activate at:
    https://ubuntu.com/livepatch

81 packages can be updated.
0 updates are security updates.

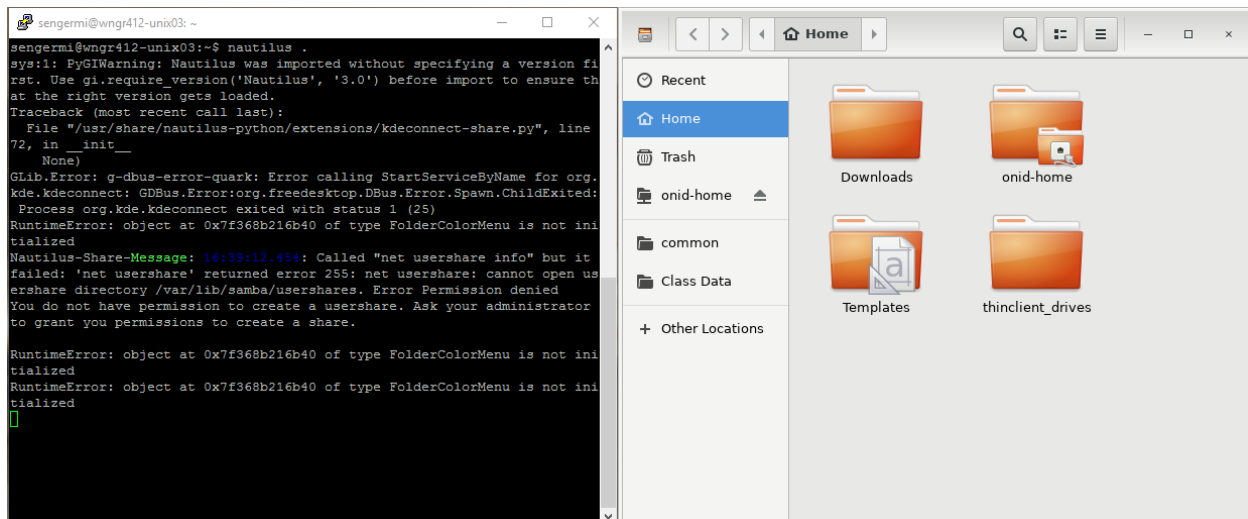

*** System restart required ***
Last login: Thu Jan 24 16:35:21 2019 from 10.206.48.94
sengermi@wngr412-unix03:~$

```

As a quick check to see if the handshake between putty and Xming is working properly, in the command line, enter -

```
nautilus .&
```

If everything is functioning properly, you'll see the Ubuntu file explorer pop up on screen.

You are now ready to transfer the OpenMX files from the CoSINe server to your onid files. Close the nautilus window to get the terminal input ready to go again.

1.3 Installation of ssh software on Mac OS and opening an ssh session

Running ssh from a Mac with an X server requires the installation of third party software. A common way of using ssh with an X server is with XQuartz. You can download it from here –

<https://www.xquartz.org/>

Once it is installed, run XQuartz and open the X terminal from the application drop-down menu. Start an ssh session by entering at the XQuartz command line –

```
ssh -Y ONID@wngr412-unixXX.science.oregonstate.edu
```

where **ONID** is your onid username and **XX** is the 412 computer number assigned to you. This should change your command line to reflect the new PC you are entering commands to.

As a quick check to make sure everything is working properly, in the command line, enter -

```
nautilus . &
```

If everything is good to go, you'll see the Ubuntu file explorer pop up on screen.

2 OpenMX File Transfer

OpenMX software is preinstalled on the computers in WNGR 412, but your account is not preloaded with the files OpenMX requires to run correctly. We have preloaded the OpenMX files onto the CoSiNe server, and it can be copied from there. Essentially, you need only follow this procedure once.

2.1 Copy the files

Open a terminal program on (or begin an ssh session with) a WNGR 412 computer, and enter

```
cp -R /common/ph575/openmx3.7 /home/ONID/
```

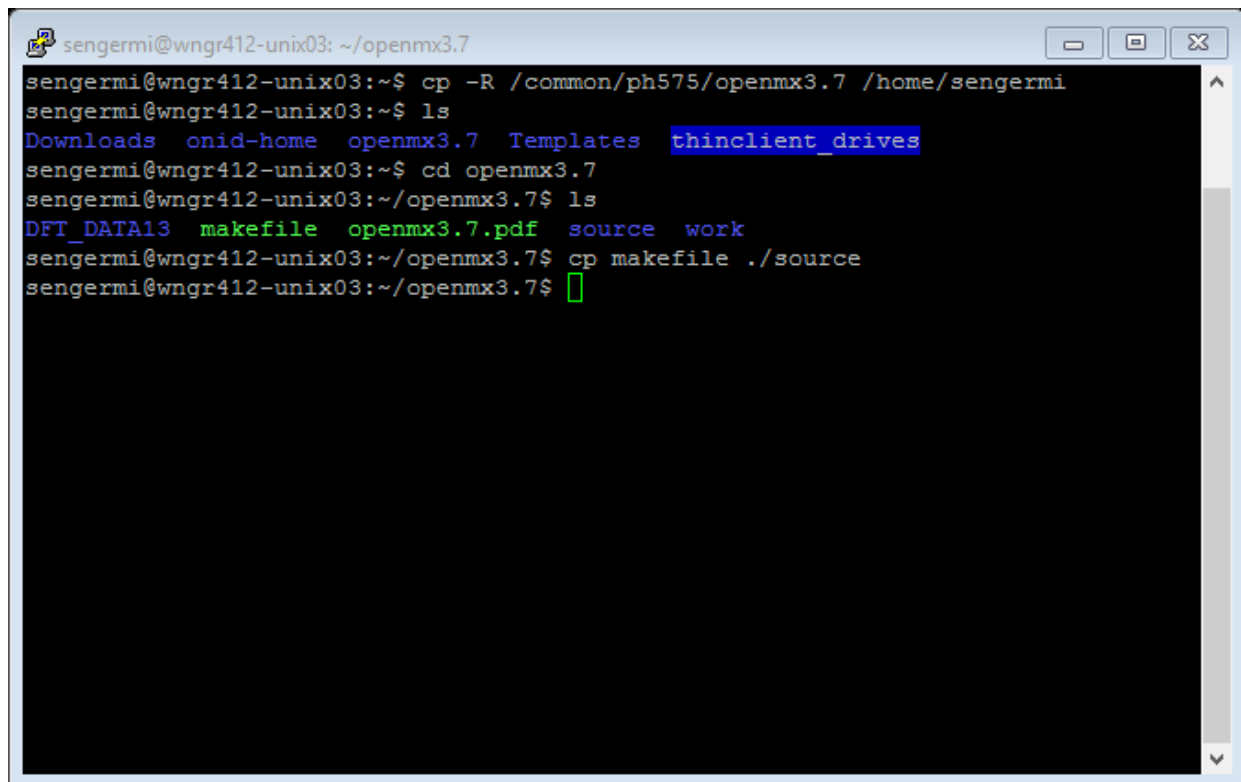

Note that the space between `/common/ph575/openmx3.7` and `/home/ONID/` is necessary. Here, **ONID** is your onid username. This will copy the OpenMX folder to your home folder. The files in your home folder can be accessed from any of the computers in WNGR 412. To make sure the transfer worked, navigate to your home folder and list the files located there. Enter the following

```
cd /home/ONID/openmx3.7  
ls
```

You should see the openmx3.7 folder contents listed as shown below.

Now as a last step you need to copy a makefile into the source folder for later use.

```
cp makefile ./source
```

```
sengermi@wngr412-unix03: ~/openmx3.7  
sengermi@wngr412-unix03:~$ cp -R /common/ph575/openmx3.7 /home/sengermi  
sengermi@wngr412-unix03:~$ ls  
Downloads  onid-home  openmx3.7  Templates  thinclient_drives  
sengermi@wngr412-unix03:~$ cd openmx3.7  
sengermi@wngr412-unix03:~/openmx3.7$ ls  
DFT_DATA13  makefile  openmx3.7.pdf  source  work  
sengermi@wngr412-unix03:~/openmx3.7$ cp makefile ./source  
sengermi@wngr412-unix03:~/openmx3.7$
```

2.2 Methane Test Calculation

OpenMX sorts its files into two main folders named source and work. The source folder contains all the software that is needed for running calculations and the work folder contains all the input and output material data files. You need to start in work to run the test calculation.

```
cd work
```

You need to run the test calculation on a preloaded material data file for molecular methane called **Methane.dat**. Execute the calculation via

```
mpirun -np 1 openmx Methane.dat > met.std &
```

The output of this calculation is contained across several files. To check if the calculation worked properly, you need to open the one named **met.out**. One way to find and open the file is with the built-in file browser program nautilus. Open this program in the current directory with –

```
nautilus . &
```

The “.” after the nautilus command initiates the program in the directory you’re currently working in. The “&” lets you continue using the command line if you’re using ssh. Now using the file browser, find and open **met.out**. There are more concise ways of doing this at the command line; for those of you that are well versed in Linux, feel free to navigate directories and manage your files in the way you think is best.

The table in this file labeled “Total energy” should match the one shown in the test calculation section of the OpenMX 3.7 user manual (http://www.openmx-square.org/openmx_man3.7/node16.html) which is shown below.

```
*****
Total energy (Hartree) at MD = 1

If your outputs match the manual’s, then you’re ready to test out calculations of bulk material properties.

3 Basic Parameter Input for Calculation of Bulk Material Properties

OpenMX does bulk material property calculations by operating on input data files with executables that correspond to a desired material property. These files are stored in either the source or work folders in the OpenMX file. Source generally contains all of the code that OpenMX uses to make calculations. Work contains the input and output files used in and produced by the OpenMX calculations. A `.dat` file contains all the needed material information to run a calculation. When OpenMX is installed, it comes preloaded with several material data files in the work folder. Running OpenMX on a material `.dat` file can generate band structures, density of states, fermi surfaces, electric transport properties, spin densities, electric field responses, and more.

For the purposes of this tutorial, we will be using the data file for diamond, `Cdia.dat` to calculate diamond's band structure and density of states. Remember to save any changes you make to this file before running any calculations. Later, when you want to run material property calculations for a material of your choice, you'll need to generate a new `.dat` file with input data corresponding to the desired material, then run OpenMX on that file in the same ways we handle `Cdia.dat`. That process is detailed in section 5 of the tutorial.

In this example, we are running all OpenMX operations on files contained in the work folder, which leads to all example calculation output files also being generated in the work folder. Going forward beyond this example, it would be best to organize your input/output files into subfolders within work, otherwise your organization will be a nightmare.

3.1 Baseline Material Parameter Input

First, you'll need to examine and edit the preloaded input file for diamond, which is in the work directory. Open this file by executing `gedit` on the `Cdia.dat` file.

```
cd
cd openmx3.7/work
gedit Cdia.dat
```

The file should be open for editing in front of you. The first three sections detail (i) the file information, (ii) which atoms are in the material, (iii) where the atoms are located. The first section is there to make sure programs executing the calculations can figure out what to name the output files.

```
#
# File Name
#
System.CurrentDirectory ./ # default=./
System.Name cdia # default=1 (1-3)
level.of.stdout 1 # default=1 (1-3)
level.of.fileout 0 # default=1 (0-2)
```

All the default options should work regardless of the material choice, but it's important to understand that the input of `System.name` will be the same as the names of the output files. You may change this to whatever you want your output files to be named, however this tutorial assumes that `System.name` has been left as `cdia`.

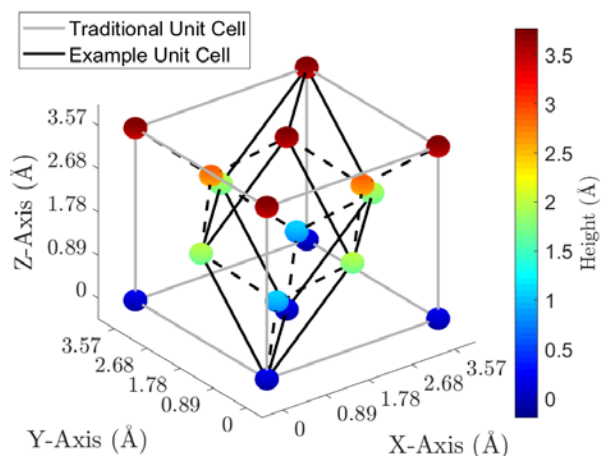

```
#
# Definition of Atomic Species
#
Species.Number      1
<Definition.of.Atomic.Species
C   C5.0-s2p2d1   C CA13
Definition.of.Atomic.Species>
```

The number of unique atoms in the material are specified by `Species.Number`. Below the `Species.Number` there is a table that tells the OpenMX programs which files to access to get the correct data for each atom named `Definition.Atomic.Species`. The first column simply specifies the atomic symbol. The second contains the name of the data file holding information on the pseudo-atomic orbitals (PAOs) that correspond to the atom, and the third specifies the data file containing the fully relativistic pseudopotentials (VPS). These file names aren't entirely intuitive, but OpenMX has supplied a catalog of the different PAO and VPS files for most atoms on their website at http://www.jaist.ac.jp/~t-ozaki/vps_pao2013/. Use this as a reference when you are generating your own material data files. To add more atoms to the system, simply add more rows into this table, each specifying atomic species, then the PAO file, then the VPS file. See the figure below for an example from NaCl.

```
#
# Definition of Atomic Species
#
Species.Number      2
<Definition.of.Atomic.Species
Na   Na9.0-s2p2   Na_CA13
Cl   Cl7.0-s2p2d1 Cl_CA13
Definition.of.Atomic.Species>
```

The last step in material specification is the input of atomic locations in the material, which occurs in the "Atoms" section of the data file. The number of the atoms in the primitive unit cell is specified by `Atoms.Number`. The unit of the input lengths, specified by `Atoms.SpeciesAndCoordinates.Unit`, can take either Angstroms (Ang) or atomic units (AU). Next is a table that gives the actual locations.

```
#
# Atoms
#
Atoms.Number      2
Atoms.SpeciesAndCoordinates.Unit  Ang # Ang|AU
<Atoms.SpeciesAndCoordinates
1  C  0.000  0.000  0.000  2.0 2.0
2  C  0.890  0.890  0.890  2.0 2.0
Atoms.SpeciesAndCoordinates>
Atoms.UnitVectors.Unit  Ang # Ang|AU
<Atoms.UnitVectors
1.7800  1.7800  0.0000
1.7800  0.0000  1.7800
0.0000  1.7800  1.7800
Atoms.UnitVectors>
```

The unit cell used in this example contains two atoms in the basis, thus `Atoms.SpeciesAndCoordinates` is a table with only two rows. The first column in this table gives the index for each atom, and the second is the atomic species. The third, fourth, and fifth are the x, y, and z coordinates of the atoms in the unit cell, respectively. The sixth and seventh columns are the number of initial up spins and number of initial down spins. The sum of the last two columns should add to the total number of valence electrons for each atom.

The second table in this section `Atoms.UnitVectors` has columns that are simply the x, y, and z components of the primitive vectors of the lattice. The unit cell used in this example (outlined in red above) is not the traditional diamond cubic unit cell normally shown (outlined in blue above), but only one octant of it, thus the lattice vectors in the example are modified to give the correct tessellation (see the image above). These parameters can be found on the crystallography open database for most materials at <http://www.crystallography.net>.

3.2 The “SCF or Electronic System” and “MD or Geometry Optimization” Sections

The sections labeled “SCF [Self-Consistent Field] or Electronic System” and “MD [Molecular Dynamics] or Geometry Optimization” detail the calculation methods and system variables that OpenMX uses for all the material property calculations. The default options should be sufficient for most calculations, so try those first. Please see the OpenMX manual for a more detailed explanation of each of these parameters at http://www.openmx-square.org/openmx_man3.7/node21.html. For this example, none of the parameters need to be changed.

```
#
# SCF or Electronic System
#

scf.XcType          LDA          # LDA|LSDA-CA|LSDA-PW|GGA-PBE
scf.SpinPolarization off          # On|Off|NC
scf.ElectronicTemperature 300.0   # default=300 (K)
scf.energycutoff     150.0        # default=150 (Ry)
scf.maxIter          100          # default=40
scf.EigenvalueSolver band         # DC|GDC|Cluster|Band
scf.Kgrid             7 7 7       # means n1 x n2 x n3
scf.Mixing.Type       rmm-diisk    # Simple|Rmm-Diis|Gr-Pulay|Kerker|Rmm-Diisk
scf.Init.Mixing.Weight 0.30        # default=0.30
scf.Min.Mixing.Weight 0.001        # default=0.001
scf.Max.Mixing.Weight 0.700        # default=0.40 [
scf.Mixing.History     7           # default=5
scf.Mixing.StartPulay  5           # default=6
scf.criterion         1.0e-10      # default=1.0e-6 (Hartree)

#
# MD or Geometry Optimization
#

MD.Type              nomd          # Nomd|Opt|NVE|NVT_VS|NVT_NH
MD.maxIter            1            # default=1
MD.TimeStep           1            # default=0.5 (fs)
MD.Opt.criterion      1.0e-5       # default=1.0e-4 (Hartree/bohr)
```

3.3 The “Band dispersion” Section

The band structure calculation parameters are entered in the “Band dispersion” section. The first step is enabling the band dispersion output, so ensure that `Band.dispersion` is set to on.

```
#
# Band dispersion
#
Band.dispersion on          # on|off, default=off
<Band.KPath.UnitCell
3.56  0.00  0.00
0.00  3.56  0.00
0.00  0.00  3.56
Band.KPath.UnitCell>
# if <Band.KPath.UnitCell does not exist,
#   the reciprocal lattice vector is employed.
Band.Nkpath 5
<Band.kpath
25  0.0 0.0 0.0  1.0 0.0 0.0  g X
25  1.0 0.0 0.0  1.0 0.5 0.0  X W
25  1.0 0.5 0.0  0.5 0.5 0.5  W L
25  0.5 0.5 0.5  0.0 0.0 0.0  L g
25  0.0 0.0 0.0  1.0 0.0 0.0  g X
Band.kpath>
```

`Band.Kpath.UnitCell` specifies a set of primitive vectors for the reciprocal lattice that will be used during the band structure calculation, each row being one vector. If you delete this table and the surrounding keyword brackets then OpenMX will use the primitive vectors specified in the “Atoms” section instead.

The next step is to set the path through k-space for which the band structure is calculated. `Band.Nkpath` sets the number of sections that comprise the path, and the table `Band.kpath` sets the parameters for each path section. The number set by `Band.Nkpath` should be equal to the number of rows in `Band.kpath`. The first column of the table specifies the number of k-points that the k-path section will be discretized into. The second, third, and fourth are the coordinates of the starting k-point and the fifth, sixth, and seventh are the coordinates of the ending k-point, both given as `kx ky kz`.

Image of an FCC Brillouin zone taken from
https://en.wikipedia.org/wiki/Brillouin_zone

The eighth and ninth columns specify the labels given to the beginning and ending k-points for each path section. Keep in mind that some locations in k-space all have labels that are specific to certain points within the first Brillouin zone. The figure above shows the k-point labels in the Brillouin zone for an FCC unit cell. The k-path used in the carbon diamond example goes as $\Gamma \rightarrow X \rightarrow W \rightarrow L \rightarrow \Gamma \rightarrow X$ (note that “g” is used for Γ). An overview of the labels for some common lattices is given on Wikipedia at https://en.wikipedia.org/wiki/Brillouin_zone.

3.4 The “DOS and PDOS” Section

The density of states (DOS) calculation is straightforward and the `.dat` file only requires three input parameters in the “DOS and PDOS” section. The first is a switch to enable or disable the DOS output. By default, it is set to `off`, so delete the word `off` and replace it with `on`. `Dos.Erange` sets the range of energies in electronvolts over which the DOS is calculated. The default should be fine but you may change it as needed. `Dos.Kgrid` sets the discretization resolution of the grid comprising Brillouin zone in k-space in the form `n1 n2 n3`. Higher resolutions will take longer but will increase precision.

```
#
# DOS and PDOS
#
Dos.fileout          on          # on|off, default=off
Dos.Erange           -25.0 20.0  # default = -20 20
Dos.Kgrid             12 12 12   # default = Kgrid1 Kgrid2 Kgrid3
```

3.5 Save and Close

Remember to save the `.dat` file before running calculations with OpenMX. Close the `.dat` file and the nautilus browser to get back to the command line.

4 Basic Calculations of Bulk Material Properties

Once you have a completed data file, all that remains is to run the SCF (self-consistent field) calculations with OpenMX and display the output data. The example calculations done in this section assume that the input file for carbon diamond **Cdia.dat** has already been setup as demonstrated in the previous section.

4.1 Band Structure Calculation

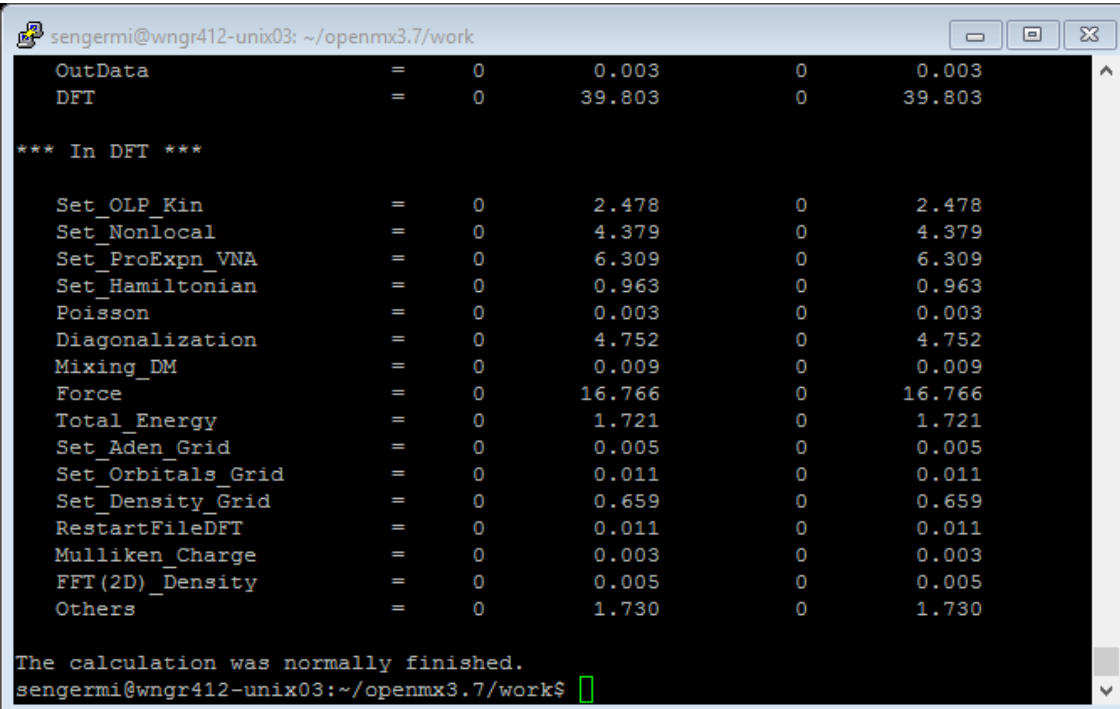

You need to run the SCF calculation with the **Cdia.dat** input file. First navigate to the work directory.

```
cd  
cd openmx3.7/work
```

Then execute the OpenMX SCF calculation with

```
openmx Cdia.dat
```

You should see a long output in the command line that terminates with “The calculation was normally finished”. This will generate an output file named **cdia.Band** if it worked correctly.

```
sengermi@wngr412-unix03: ~/openmx3.7/work

The calculation was normally finished.  
sengermi@wngr412-unix03:~/openmx3.7/work$
```

Now that this step is complete, all the needed data to show the band structure has been generated, so all that’s left is to visualize it. To do this, OpenMX comes with a file that, when compiled, generates an executable program that converts the band structure data into a gnuplot script. Navigate the command line to the source folder.

```
cd ..  
cd source
```

Now compile the file named **bandgnu13.c** – this will generate an executable named **bandgnu13**. You might see a lot of warnings here, but as long as there are no errors you are good to go.

```
gcc bandgnu13.c -lm -o bandgnu13
```

This file needs to be copied over to the work folder.

```
cp bandgnu13 /home/ONID/openmx3.7/source /home/ONID/openmx3.7/work
```

Now go back to the work folder to run the executable you copied on the band structure data generated by running openmx on **Cdia.dat**.

```
cd ..  
cd work  
./bandgnu13 cdia.Band
```

This should produce two output files. The one named **cdia.GNUBAND** is a script for Gnuplot that pulls the band structure data from the other output file named **cdia.BANDDAT1** (use `ls` to make sure these files are here, they may not appear in nautilus if you're using ssh). Before plotting the data, we need to edit **cdia.GNUBAND**. Open the **cdia.GNUBAND** file with

```
gedit cdia.GNUBAND
```

Change the top line to match the one in the figure below. Also edit the “`set yra`” line to a more reasonable set of energies (-25 to 20 eV should do nicely), then save and close it. For more information on gnuplot, see the documentation [here](#). Most of the settings changed by these .GNUBAND files are listed in the Set-show section (pg 111).

```
set style data lines  
set nokey  
set zeroaxis  
set ytics 1  
set mytics 5  
set xra [0.000000:3.804167]  
set yra [-25:20]  
set ylabel "eV"  
set xtics ("g" 0.000000, "X" 0.933966, "W" 1.400949, "L" 2.061363,  
"g" 2.870201, "X" 3.804167)  
plot "cdia.BANDDAT1"  
pause -1]
```

Now at the command line plot the data with gnuplot. You should then see a window displaying the band structure of the material.

```
gnuplot cdia.GNUBAND
```

If you like, you can use your own plotting software instead of Gnuplot to plot the data contained in `cdia.BANDDAT1`. Matlab and Python are installed on the 412 machines, which might be helpful for that. You can also drag the `cdia.BAND` file into the OpenMX viewer (www.openmx-square.org/square/index.html) to easily visualize the data, but the formatting options are limited here.

4.2 Density of States Calculation

Before starting the DOS calculation make sure that the `Dos.fileout` keyword in `Cdia.dat` (near the end of the file) is set to on (see tutorial section 3.4). If you haven't done so already, run the SCF calculation on the data file in the work directory.

```
cd
cd openmx3.7/work
openmx Cdia.dat
```

The SCF calculation outputs a couple files needed for the DOS calculations: `cdia.Dos.val` and `cdia.Dos.vec`. Like the band structure calculations, you need to compile an executable program (`DosMain`) from a file preloaded into the source directory (`DosMain.c`). If `DosMain` doesn't already exist in your work directory, go to the source directory and generate the executable with `make` –

```
cd
cd openmx3.7/source
make DosMain
```

You may see some warnings while this is executing. Make sure the DosMain executable is now in the directory with `ls`, if it is, you're OK to proceed. Copy **DosMain** from the source folder to the work folder

```
cp DosMain /home/ONID/openmx3.7/work
```

Now you can run the DOS calculation from the work folder via –

```
cd ..
cd work
./DosMain cdia.Dos.val cdia.Dos.vec
```

```
sengermi@wngr412-unix03: ~/openmx3.7/work
sengermi@wngr412-unix03:~/openmx3.7/source$ cp DosMain /home/sengermi/openmx3.7/ ^
work
sengermi@wngr412-unix03:~/openmx3.7/source$ cd ..
sengermi@wngr412-unix03:~/openmx3.7$ cd work
sengermi@wngr412-unix03:~/openmx3.7/work$ ./DosMain cdia.Dos.val cdia.Dos.vec
Max of Spe_Total_CNO = 13
1 1 101 102 103 101 102 103 201 202 203 204 205
<cdia.Dos.val>
<cdia>
1 Which method do you use?, Tetrahedron(1), Gaussian Broadening(2)
2 Do you want Dos(1) or PDos(2)?
2
Number of atoms=2
3 Which atoms for PDOS : (1,...,2), ex 1 2
1
pdos_n=1
1
<Spectra_Tetrahedron> start
make cdia.PDOS.Tetrahedron.atom1.s1
make cdia.PDOS.Tetrahedron.atom1.p1
make cdia.PDOS.Tetrahedron.atom1.p2
make cdia.PDOS.Tetrahedron.atom1.p3
make cdia.PDOS.Tetrahedron.atom1.d1
make cdia.PDOS.Tetrahedron.atom1.d2
make cdia.PDOS.Tetrahedron.atom1.d3
make cdia.PDOS.Tetrahedron.atom1.d4
make cdia.PDOS.Tetrahedron.atom1.d5
make cdia.PDOS.Tetrahedron.atom1
sengermi@wngr412-unix03:~/openmx3.7/work$
```

The program will then execute, but you need to enter some directions to the program as it runs (these steps are labeled in the figure above).

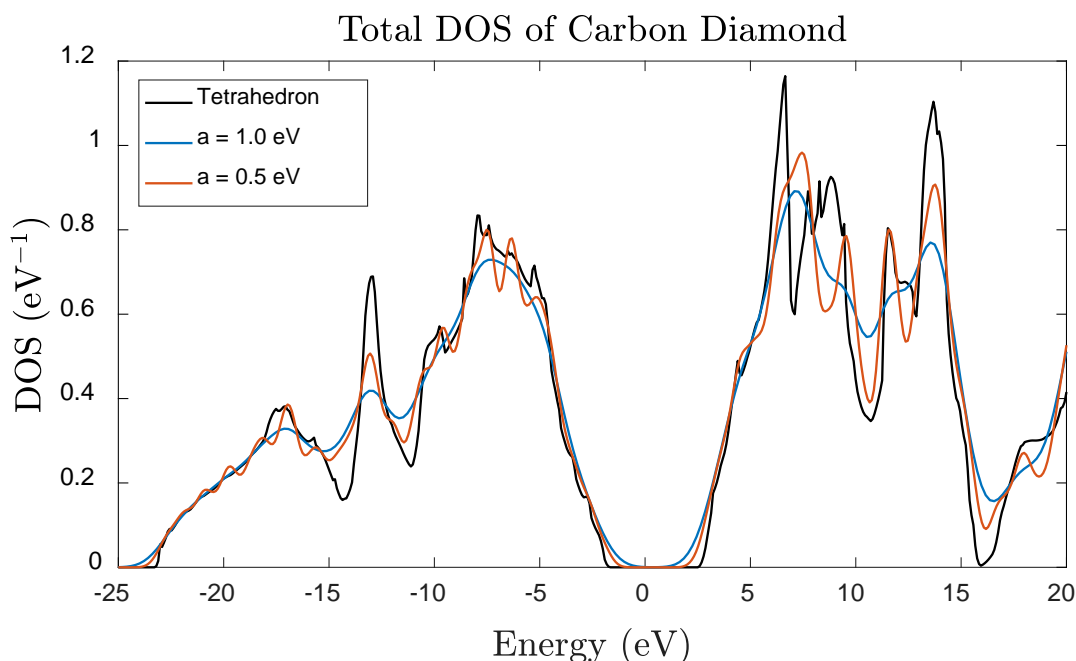

1. The software offers the option to run the calculation with either the tetrahedron or Gaussian broadening algorithm. These are two ways of approximating the potential wells of atoms in the lattice. For this example, you should proceed with the tetrahedral method because that seems to work best.

If you enter Gaussian broadening instead of tetrahedral, you'll be prompted to enter the "value of Gaussian". The Gaussian broadening functions are of the form $\exp(-(E/a)^2)$, and the "value of Gaussian" specifies the value of a . The plot below shows the DOS output for several choices you can make here. See the manual for more information. You'll need to research on your own to find out which is best for other materials.

2. You can either run the total DOS for the material, or you can run the partial DOS (PDOS) to get the density of states for individual atoms and orbitals.

PDOS only:

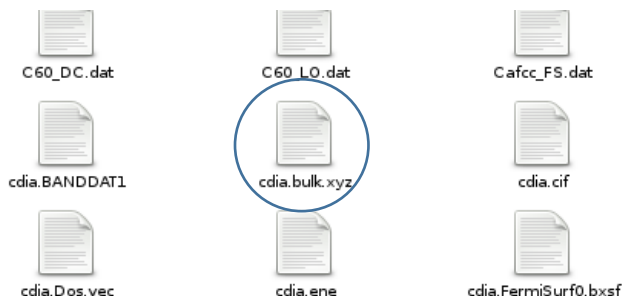

3. The software automatically detects how many atoms are in the unit cell you specified. Select which atom you want to run the PDOS for.

After completing these steps the software prints out a list of data files that contain the partial density of states. Each of these are labeled with the orbital they correspond to. The last one contains the total density of states for the atom you selected. These files contain three columns. The first is the energy given in electronvolts. The second contains the density of states at each energy point in units of eV⁻¹. The third contains the integrated density of states through the corresponding energy. OpenMX doesn't have a gnuplot converter for this data, so use your favorite plotting software to display it. Matlab can read the data with the `d1mread` function and Microsoft Excel can open the data files with fixed width delimitation.

4.3 Lattice Visualization with XCrySDen

The SCF calculation will automatically output a couple visualization files – **cdia.bulk.xyz** and **cdia.xyz**. .xyz files are common among DFT and molecular dynamics software and many programs can read them.

The computers in Weniger 412 already have XCrySDen installed. This software can be used to visualize several output files from OpenMX including .xyz, .md, .cube, and .xsf. There are some bugs that do not allow this software to run over putty with Xming easily, so you should use the computers in 412 directly without ssh. If you're working on these machines via ssh you should use the OpenMX Viewer instead.

Running the software is straightforward. Simply open a terminal and run XCrySDen at the command line.

xcrysden

```

sengermi@wngr412-pc19: ~

```

Now an empty XCrySDen window will open. Select File>Open Structure...>Open XYZ and open **cdia.bulk.xyz** under the OpenMX work directory.

This will display a few periods of your material structure.

5 Simulating your own materials

Once you are ready to simulate materials that are not preloaded into the OpenMX work folder (as you will need to do for your project!), you will need to generate a new `.dat` file for the material. This includes finding the atom species, the location of the atoms, pseudopotentials, the k-space path for the dispersion relationship, and the unit vectors, among other things for chosen material. There are databases loaded with these parameters for lots of materials.

5.1 Getting unit cell information from `.CIF` files for new materials

In the field of crystallography, there are two common languages used to define the conventional unit cell of a crystal structure. The first, which I'll refer to as `abc`, pairs a primitive unit cell with a space group, which contains information about the needed rotations and tessellations needed to produce the conventional unit cell. The second defines the positions of all the atoms in the conventional unit cell via Cartesian coordinates without the need to specify a space group; I'll call this `xyz`.

OpenMX needs a unit cell that is specified in `xyz`, meaning that the unit vectors and the atom positions must be specified in Cartesian coordinates. One of the best resources for obtaining crystal structure data, the Crystallography Open Database (crystallography.net) or the Materials Project (<https://materialsproject.org/>), but the data stored in these databases is distributed in `.cif` files that use the `abc` convention. Any `.cif` file downloaded from this database will specify a unit cell by giving three tessellation lengths (a , b , and c) and the angles between the tessellation directions (α , β , and γ), referred to collectively as lattice constants (see the figure below).

To use the information contained in these `.cif` files in OpenMX, you need to convert the lattice constants to Cartesian unit vectors (this is separate from the atom positions). If we let the side length a lie on the x-axis and put b in the x-y plane, then the cartesian unit vectors can be found as follows –

$$\vec{a} = a\hat{x}$$

$$\vec{b} = b(\cos \gamma \hat{x} + \sin \gamma \hat{y})$$

$$\vec{c} = c \left(\cos \beta \hat{x} + \frac{\cos \alpha - \cos \gamma \cos \beta}{\sin \gamma} \hat{y} + \left(\sin^2 \beta - \frac{(\cos \alpha - \cos \gamma \cos \beta)^2}{\sin^2 \gamma} \right)^{1/2} \hat{z} \right)$$

These vectors can be added to the `<Atoms.UnitVectors>` section of the `.dat` file. Now that we have the Cartesian unit vectors we need to figure out the positions of the atoms within the unit cell. The `.cif` files report the atomic locations of the primitive unit cell in fractional coordinates as shown in the figure below.

Data Table Column Titles	Atom Location Data
_atom_site_label	Mo1 Mo+4
_atom_site_type_symbol	S1 S-2
_atom_site_fract_x	0.3333 0.3333
_atom_site_fract_y	0.6667 0.6667
_atom_site_fract_z	0.25 0.623
_atom_site_occupancy	1 1
_atom_site_U_iso_or_equiv	0.0 0.0

Each row in the data table gives the coordinates of a primitive unit cell atom as fractions of a , b , and c in the third, fourth, and fifth columns, respectively. Since OpenMX only tessellates the unit cell, the primitive unit cell may not contain all of the atom locations that OpenMX needs to perform the calculation correctly. For this example, the `.cif` file for MoS₂ has only two atoms detailed, but there are six atoms that need to be detailed to generate the lattice purely by tessellating the unit cell. OpenMX has a web app (the OpenMX viewer) that allows us to convert the position data in a `.cif` file to Cartesian coordinates for all atoms needed easily at (<http://www.openmx-square.org/viewer/index.html>). You can also use this as an alternative to XCrySDen for crystal visualization. Simply download the desired `.cif` file from a database and drag it into the OpenMX Viewer window.

The use of Google Chrome is highly recommended due to its performance.

Welcome to OpenMX Viewer

Drag & drop here the following file:
a.dat, xyz, ed, md, or cif file

SuperCell: 1x1x1, 1x1x1, 1x1x1, Atoms: 100, Bonds: 100, Number: 100, Symbol: BGC, Boxes: 100, Atom Size: 1.0, Bond Thickness: 1.0, Bond Color: BGC, Cells: 1x1x1, Axes: Perspective, Structure: Dynamics, Net Charge: 0, Spin: 0, Force: Velocity, Rot on x: 0, Rot on y: 0, Rot on z: 0, Save: none, OpenMX website, Rotate: click+drag, Zoom: scroll, Translate: ctrl+click+drag. Note: click the middle button for Safari

You'll get a popup window asking if you want OpenMX Viewer to draw the conventional unit cell; just press "OK". You should then see the conventional unit cell of the material. There are a lot of helpful tools built into this application, but for now, we just need the position data. You can download the data as a **.xyz** file with the toolbar at the bottom by selecting "xyz" from the "Save" dropdown menu.

Save the file and open it with `gedit` or another formatting word processor. These `.xyz` files contain a nicely formatted table containing the Cartesian coordinates of the atoms in the conventional unit cell (all units here are in angstroms).

Number of Atoms		x-position	y-position	z-position
6	Mo	-0.0001585	1.8297145	3.0810000
	Mo	1.5843416	0.9147200	9.2430000
	S	-0.0001585	1.8297145	7.6778520
	S	1.5843416	0.9147200	1.5158520
	S	-0.0001584	1.8297145	10.8081480
	S	1.5843416	0.9147200	4.6461480

The number in the header just specifies the number of atoms in the conventional unit cell. You can enter these positions as is into an OpenMX `.dat` file in the `<Atoms.SpeciesAndCoordinates>` section to run your calculations.

5.2 Generating custom k-paths

You can find the coordinates of the k-points for materials by looking up their space group number in the Bilbao Crystallographic Server database (http://www.cryst.ehu.es/cryst/get_kvec.html). Space groups can usually be found on the Wikipedia page for a given material and they are listed in the .cif files obtained from the Crystallography open database. To get the coordinates of the high-symmetry k-points, click the “comparative listing of k-vector types” button once you’ve entered the space group number for a material. The labels in the leftmost column correspond to the k-point names, and the values on the rightmost column correspond to the k_x , k_y , k_z coordinate values that need to be entered into `Band.kpath`.

Bilbao Crystallographic Server → The k-vector types and Brillouin zones of the space groups Help

The k-vector types and Brillouin zones of the space groups

Brillouin-zone databases of space groups

The Bilbao-zone database offers k-vector tables and figures which form the background of a classification of the irreducible representations of all 230 space groups.

The space groups are specified by their sequential number as given in the *International Tables for Crystallography, Vol. A*. You can give this number, if you know it, or you can choose it from the table with the space group numbers and symbols if you click on choose it.

To get the k-vector types described in three different basis (primitive, conventional and ITA) click on the bottom *Comparative listing of k-vector types*.

Please, enter the sequential number of the space group as given in *International Tables for Crystallography, Vol. A*, or choose it:
